Where the World's Used Clothes End Up

By Daniel · 2026-09-21 · 262 words · L2

중고 의류가 도착하는 나라

Every year, wealthy countries export billions of dollars' worth of secondhand clothing to developing nations. These garments — sorted, bundled, and shipped in large bales — travel to markets across Africa, South Asia, and Latin America, where they are resold at low prices. For many buyers, they represent affordable fashion. For the countries receiving them, the story is more complicated.

Ghana is one of the world's largest destinations for used clothing. The Kantamanto market in the capital, Accra, is among the biggest secondhand clothing markets on the planet. Traders buy bales sight unseen

from importers, not knowing what is inside until they cut them open. A large share of what arrives turns out to be worn out or simply unsellable.

Clothing that cannot be sold often ends up in landfills or washes into rivers and eventually onto beaches. Environmental groups have documented serious pollution along Ghana's coastline, where piles of discarded textiles have built up over the years. Similar scenes have been reported in Kenya and other parts of sub-Saharan Africa.

Chile's Atacama Desert presents another striking example. Used

clothing enters through the port of Iquique, a duty-free zone, and floods local markets. Whatever remains unsold is frequently dumped in the desert, creating massive textile waste fields that are visible from the air.

Supporters of the secondhand trade argue that it creates jobs and gives low-income households access to affordable clothes. Critics, however, say rich countries are effectively exporting their waste problem. As fast fashion continues to drive up clothing production globally, the pressure on receiving countries is only expected to grow.

When Pro Sports Teams Leave Their Cities

By Daniel · 2026-09-21 · 150 words · L1

프로 구단의 연고지 이전

When a professional sports team moves to a new city, it can break the hearts of fans left behind. This is called a franchise relocation, and it happens more often than many people realize. In the United States, teams in major leagues like the NFL, NBA, and MLB have moved dozens of times over the past several decades.

One recent example is the Oakland Athletics baseball team. After more than 50 years in Oakland,

California, the team relocated to Las Vegas in 2025. Many longtime fans felt angry and abandoned. Local businesses near the old stadium also lost customers who used to come for game days.

Teams usually move because of money. Owners look for cities that offer newer stadiums, larger fan bases, or better financial deals. However, the original city often loses tax income and jobs as a result. Some fans never support the team again after it leaves.

Panama Canal Faces a Growing Water Crisis

By Daniel · 2026-09-21 · 290 words · L2

파나마 운하의 가문

The Panama Canal is one of the world's most important shipping routes, connecting the Atlantic and Pacific Oceans through a narrow strip of land in Central America. Each year, thousands of cargo ships pass through it, carrying goods that affect prices and supply chains around the globe. But a serious water shortage is now threatening its ability to operate normally.

The canal does not use saltwater from the sea. Instead, it depends on freshwater from Gatun Lake, a large artificial lake created nearly a century ago. When ships pass through the canal's locks, huge amounts of water are released into the

ocean. This means the lake must be constantly refilled by rainfall and river flows.

In 2023, an unusually strong El Niño weather pattern brought severe drought to the region. Water levels in Gatun Lake dropped sharply, forcing canal authorities to reduce the number of ships allowed to pass each day by more than a third. Some vessels waited weeks for their turn, causing delays and rising shipping costs worldwide.

To prevent similar disruptions in the future, Panamanian authorities have proposed building a new dam to create an additional water reservoir. However, the plan has faced strong opposition

from farming communities whose land would be flooded. Local residents worry about losing their homes and livelihoods, turning the water shortage into both an environmental and a social issue.

Climate scientists warn that droughts in the region could become more frequent as global temperatures rise. For a waterway that handles roughly three percent of global trade, finding a reliable long-term solution is urgent. The challenge facing Panama — balancing the canal's needs with those of its own people — reflects a tension that many countries around the world are beginning to feel.

Satellite Internet Reaches the World's Most Remote Places

By Daniel · 2026-09-21 · 262 words · L2

위성 인터넷이 닿는 오지

For roughly one-third of the world's population, reliable internet access remains out of reach. Many of these people live in mountainous regions, isolated islands, or vast rural areas where building cable or fiber networks is simply too costly. Satellite internet is now changing that picture.

Traditional satellites orbit at about 35,000 kilometers above Earth. At that distance, signals take a noticeable amount of time to travel back and forth, making video calls and real-time applications frustrating. A newer generation of satellites, however, flies much lower — at altitudes between

500 and 1,200 kilometers — and delivers far faster, more responsive connections.

Companies like SpaceX, with its Starlink service, and Amazon, with its Project Kuiper, are launching hundreds of these low-Earth orbit satellites to form large networks in space. Starlink already serves customers in over 100 countries, including remote communities in northern Canada, rural Alaska, and parts of sub-Saharan Africa that had little or no internet before.

The benefits go beyond convenience. Schools in isolated villages can access online learning resources. Healthcare workers can send patient data to distant

hospitals. Analysts note that reliable connectivity in remote areas can raise local economic activity and improve public services significantly.

Still, challenges remain. Monthly subscription costs can be high for low-income communities, and the equipment needed to connect is not cheap. Some experts also point to concerns about space congestion, as thousands of new satellites increase the risk of collisions in orbit. How governments and companies manage these issues will shape whether satellite internet truly delivers on its promise for the world's most disconnected communities.

The World Is Running Out of Sand

By Daniel · 2026-09-21 · 300 words · L3

사라지는 모래와 건설업

Sand is one of the most widely used natural resources on Earth, yet most people never think twice about it. Every year, the world consumes an estimated 40 to 50 billion tonnes of sand and gravel — enough to cover the entire country of England in a thick layer.

The construction industry is by far the largest user. Sand is a key ingredient in concrete, glass, and asphalt, making it essential for building roads, bridges, and cities. As urban populations have grown rapidly across Asia, Africa, and the Middle East, demand for sand has risen sharply over the past two decades.

The problem is that not all sand can be used for construction. Desert sand is too

smooth and rounded from wind erosion to bond properly in concrete. The sand that builders need comes mostly from riverbeds, lakes, and coastlines — places where extraction causes serious environmental damage.

When sand is removed from rivers faster than nature can replace it, riverbanks become unstable and fish habitats are destroyed. Surrounding farmland can also start to sink. Some rivers in Southeast Asia have already lost significant portions of their beds due to heavy mining.

The shortage has also created a black market. Criminal networks in countries such as India, Vietnam, and parts of

West Africa now control illegal sand mining operations worth billions of dollars annually. These networks are reported to be highly organized, and local officials are sometimes alleged to ignore what is happening.

Monitoring of sand extraction has struggled to keep pace with the speed of demand, leaving many vulnerable ecosystems without adequate protection.

Without stronger international regulation and wider adoption of alternatives — such as recycled materials and industrial by-products — the pressure on the world's sand supplies is likely to keep growing alongside the demand for new infrastructure.

When the Nearest Delivery Room Is Miles Away

By Daniel · 2026-09-21 · 276 words · L2

병원 없는 지역의 분만실

For many pregnant women in rural areas, the local hospital no longer offers a place to give birth. Across the United States, more than half of rural hospitals have closed their labor and delivery units in recent years, leaving entire communities without access to maternity care close to home.

This growing shortage has a name: maternity care deserts. These are counties where there are no hospitals with obstetric services and no midwives or obstetricians practicing locally. Experts say the number of such areas has been rising steadily, particularly in states with large rural populations.

Hospitals point to shrinking budgets and falling birth rates as the main reasons for closing these units. Running a safe delivery ward requires round-the-clock staffing by trained nurses, doctors, and anesthesiologists — costs that become very difficult to cover when the number of births drops below a certain level each year.

The consequences can be serious. When a complication arises during labor, every minute matters. Women in maternity care deserts may need to travel an hour or more to reach a hospital, raising the risk of dangerous outcomes for both mother and baby. Health researchers note that maternal

mortality rates tend to be higher in rural areas than in cities.

Some organizations are trying new approaches to fill the gap. Mobile health clinics, for example, have been deployed in parts of Florida to bring prenatal checkups and maternal health services directly to underserved communities. Telehealth services, which connect patients with doctors by video, are also expanding. Whether these solutions can fully replace a hospital delivery room remains an open question, but they are giving more women access to at least basic care.

Empty Storefronts Reshape City Centers Worldwide

By Daniel · 2026-09-21 · 274 words · L2

빈 상가가 늘어난 도심

Walk through many city centers today and the signs are hard to miss: boarded-up windows, faded 'For Rent' notices, and streets that once buzzed with shoppers now standing eerily quiet. The rise of empty storefronts has become one of the most visible urban challenges of the 2020s.

The shift began well before the pandemic, driven largely by the growth of online shopping. When the pandemic then forced millions of workers to stay home, foot traffic in downtown areas fell sharply, and many small businesses could no longer afford the rent. In cities like Montreal and several major American cities, vacancy rates in

downtown retail zones climbed to levels not seen in decades.

Remote work has made the problem harder to solve. When office workers no longer commute five days a week, nearby cafés, clothing shops, and service businesses lose a reliable base of customers. Some US cities have responded by waiving business registration fees or offering small grants to attract new tenants into empty units.

Urban planners suggest that the solution may involve rethinking what downtown spaces are actually for. Rather than waiting for traditional retail to return, some cities are converting empty

storefronts into community centers, co-working spaces, or small creative studios. These uses can bring people back without depending entirely on consumer spending.

The trend also raises a question worth considering: what kind of city do residents actually want? Downtown areas have historically been defined by commerce, but shifting habits may push cities toward more mixed-use neighborhoods where living, working, and leisure exist side by side. How quickly cities adapt to this new reality may determine the long-term health of their centers.

Data Centers Are Draining Our Water Supplies

By Daniel · 2026-09-21 · 262 words · L2

데이터센터가 마시는 물

Every time someone uses an AI chatbot or streams a video, a data center somewhere is working hard — and using a surprising amount of water to stay cool. These large facilities house thousands of servers that generate enormous heat, and cooling them requires water in quantities that many people would find shocking.

Data centers use water in two main ways. Some systems pump water directly through cooling equipment. Others use water to chill the air around the servers. In both cases, much of that water evaporates and is lost permanently.

The scale of this consumption is significant. A single large data center can use millions of liters of water each day — roughly as much as a small city. As AI tools become more popular and more powerful, the demand for data center capacity keeps growing, and so does their water use.

What makes this issue more complex is a lack of transparency. Most tech companies do not publicly report exactly how much water their facilities consume. Environmental groups say this makes it very difficult to assess the true impact on local water supplies,

especially in dry regions where water is already scarce.

Some companies have begun publishing annual water reports and setting reduction targets. Microsoft, for example, has pledged to replenish more water than it uses by 2030. However, critics say voluntary commitments are not enough and that stronger regulations are needed. As global demand for AI continues to rise, how the tech industry manages its water footprint will likely become one of the defining environmental questions of the decade.

Three Years of Rising Coffee Prices

By Daniel · 2026-09-21 · 277 words · L2

커피 원두 값이 오른 3년

The price of coffee has been climbing for nearly three years, and there is no clear sign of it slowing down. Arabica bean prices on global markets hit record highs in early 2025, pushing up costs for cafes and consumers around the world.

The main driver is weather. Brazil and Vietnam — the world's two largest coffee producers — have both suffered from droughts and extreme heat linked to climate change. Brazil grows more than a third of the world's coffee supply, so when its harvests fall short, global prices feel the impact almost immediately.

Vietnam is the leading producer of Robusta beans, which are used in instant coffee and espresso blends. Dry conditions there in 2023 and 2024 cut output sharply. With both major suppliers struggling at the same time, the global supply gap widened and prices rose further.

Financial investors have added pressure to the market. When traders expect shortages, they buy futures contracts — agreements to purchase coffee at a set price later. This activity pushes prices up even before the shortage actually arrives. Analysts say this kind of speculative buying has made recent price swings larger than usual.

For consumers, the effects are clear. Major coffee chains have raised their prices, and supermarket brands have followed. Some buyers in Asia and Europe are switching to cheaper alternatives, while others are simply paying more.

Experts say the deeper problem is that coffee farming has not adapted fast enough to changing climate conditions. Many growers still rely on traditional methods in regions that are becoming less suitable for the crop. Without investment in climate-resistant farming, another price spike may be only one bad harvest away.
