More Cities Are Building Dedicated Bike Lanes

By Daniel · 2026-09-28 · 271 words · L2

자전거 도로가 늘어난 도시

Across North America and Europe, cities have been steadily expanding their cycling networks, giving riders more space on roads that were once dominated by cars. The shift reflects both a change in urban planning priorities and growing public interest in sustainable transportation.

The pandemic years accelerated this trend significantly. When traffic fell sharply during lockdowns, cities saw an opportunity to reallocate road space. Montreal, Washington D.C., and Austin were among the cities that doubled or even tripled their protected bike lanes

during this period, and many of those lanes were later made permanent.

The longer-term data tells a similar story. Between 2000 and 2017, cities such as Minneapolis, Chicago, and Los Angeles more than doubled their total bike lane networks. Over the same period, paved off-road cycling trails across the United States increased by roughly six times, pointing to a sustained commitment to cycling infrastructure rather than a short-lived response to any single event.

The reasons behind this expansion go beyond encouraging exercise. Urban planners argue that well-designed cycling networks reduce traffic congestion, lower

carbon emissions, and make cities more accessible for people who cannot afford a car. Protected bike lanes — ones physically separated from motor traffic — are also associated with fewer road accidents involving cyclists.

Still, challenges remain. Critics point out that building new bike infrastructure often comes at the cost of parking spaces or car lanes, which creates conflict in busy city centers. Ensuring that cycling networks connect residential neighborhoods to workplaces and transit hubs is also seen as essential if cities want more people to make cycling a regular habit rather than just an occasional choice.

Life After Sport: What Comes Next?

By Daniel · 2026-09-28 · 295 words · L3

프로 선수의 은퇴 후 직업

For elite athletes, retirement rarely arrives gently. Many leave professional sport in their late twenties or early thirties, facing decades of working life with skills that do not always translate easily to a new career.

The physical demands of professional sport mean that most athletes retire far earlier than workers in other fields. A professional footballer, for example, typically stops competing around age 33 or 34, while most careers in other industries peak much later.

The transition is not only practical but deeply personal. An athlete's entire sense of self is often built around competition, training, and team identity. When that structure disappears, many former players

report feelings of loss, confusion, and a lack of purpose that can persist for years.

Research on career transitions shows that athletes who plan ahead tend to fare significantly better. Those who develop outside interests, pursue education, or build professional networks while still competing are more likely to find stable, fulfilling second careers.

Some paths are well known. Coaching, broadcasting, and sports management are popular choices, as they keep former athletes connected to the world they know best. Others move further afield, entering business, finance, or public service.

Korean professional athletes face particular challenges in this regard. Intense training schedules from a young age often leave limited time for academic study or other skills development, meaning many retire without a clear sense of what comes next.

Sports organisations and national associations are increasingly aware of this problem. Several have introduced career counselling programmes and educational support for active players, aiming to make retirement a planned step rather than a sudden ending.

Experts point to early intervention as the key. The earlier an athlete begins preparing for life after sport, the smoother and more confident that transition tends to be.

Rising Prices Push Sea Cucumbers Toward Extinction

By Daniel · 2026-09-28 · 263 words · L2

김값이 오른 바다

Sea cucumbers were once considered a low-value seafood, but they have become one of the most expensive marine products in the world. Demand from East Asian markets, especially China, has driven prices to extraordinary levels — some species now sell for over \$600 per kilogram.

Sea cucumbers are soft-bodied marine animals found on the ocean floor. They play a vital role in keeping coral reefs healthy by recycling nutrients in the seawater. Scientists say that when sea cucumber populations decline, reef ecosystems can deteriorate rapidly.

Despite their ecological importance, sea cucumbers are being harvested at an unsustainable rate. Between 2011 and 2016, average prices rose by roughly 16 percent, and some high-demand species tripled in value. That financial reward has pushed fishers to harvest far beyond what populations can recover from.

Illegal and unregulated fishing makes the situation worse. Experts warn that if current harvesting trends continue, several species could face extinction within decades. The United Nations Food and Agriculture Organization has listed sea cucumbers among the most at-risk marine species due to commercial overfishing.

Some countries have introduced catch limits and export bans to protect remaining populations. However, enforcement is difficult in open ocean areas, and black-market trade continues to be a serious concern. Researchers point out that truly effective protection requires international cooperation, not just national rules.

The story of sea cucumbers shows how quickly economic demand can threaten a species that most people barely notice. Their survival matters not only for biodiversity, but also for the health of coral reefs that millions of people and countless marine species depend on.

Closed Schools Find New Life as Art Spaces

폐교에 들어선 미술관

When a school closes, its empty classrooms and hallways can feel like a loss for the local community. In recent years, however, many former school buildings around the world have been given a second life as art galleries, cultural centers, and creative spaces.

One well-known example is the Woodland Cultural Centre in Ontario, Canada. The building, which once operated as a residential school, has been transformed into a museum that preserves Indigenous history and

art. Its reopening showed how a difficult past can be honored through culture rather than forgotten.

This trend is growing in many countries where falling student numbers have left school buildings empty. Turning these spaces into art venues keeps them useful and open to the public. For local residents, a former school-turned-gallery can become a new gathering place — one that connects community history with creative expression.

Cities Are Burying Power Lines Underground

By Daniel · 2026-09-28 · 120 words · L1

전선을 땅에 묻는 공사

Across the United States and many other countries, utility companies are moving power lines underground. This process, called undergrounding, is growing more common as cities seek to reduce storm-related outages. Underground lines are far less likely to be damaged by falling trees or severe weather. Workers dig trenches along roads, lay protective pipes called conduits, and then pull

electrical cables through them. Once buried, the lines are covered and the road is restored. However, this work is costly, with U.S. prices ranging from \$400,000 to \$3 million per mile. Because of this, many cities prioritize their most storm-prone or densely populated areas first. Repairing underground cables is also more difficult, since workers must find and dig up the damaged section.

The Long Wait at Grain Export Ports

By Daniel · 2026-09-28 · 293 words · L2

곡물 수출항의 줄서기

Every year, hundreds of millions of tons of grain move through the world's busiest export ports. The journey from farm to ship, however, is rarely smooth. Delays at major grain ports have become a serious problem for farmers, traders, and food importers around the world.

Grain export ports handle enormous volumes of cargo. Ships must arrive, load, and depart on a strict schedule. When something goes wrong — a strike, bad weather, or a security threat — vessels line up and wait, sometimes for days or even weeks.

The costs of waiting add up quickly. Ship owners charge daily fees called

demurrage when a vessel sits idle in port. These fees can be substantial, and farmers and exporters often have to absorb those costs, which cuts deeply into their profits.

The causes of port backlogs vary widely and can strike with little warning. Labor strikes can shut down loading terminals overnight. Security risks — such as sea mines near Ukrainian Black Sea ports during the Russia-Ukraine conflict — have forced ships to avoid entire regions. Inspection rules designed to check grain quality or enforce trade agreements also slow the process down considerably.

Small delays at a single major port can affect food supplies in countries that depend heavily on grain imports. Nations in the Middle East and North Africa, for example, rely on wheat shipped through a few key export hubs. When those hubs slow down, prices at local markets can rise sharply.

Upgrading port infrastructure and improving international coordination are among the approaches that could help reduce these bottlenecks. Better planning and investment may keep global supply chains running more reliably. For now, the queue at grain export ports remains one of the quieter but more consequential challenges in global food supply.

Islands Without Pharmacies Face Medicine Access Challenges

By Daniel · 2026-09-28 · 282 words · L3

약국이 없는 섬의 처방전

For people living on small islands far from the mainland, getting prescription medicine can be surprisingly difficult. When there is no pharmacy nearby, even a simple illness can become a serious problem.

Many inhabited islands around the world are home to only a few hundred or a few thousand residents. Because the population is small, it is rarely profitable for a pharmacy to operate there. As a result, islanders often depend entirely on the mainland for their medical supplies.

When a doctor on the island — or reached through a teleconsultation online — prescribes medicine, the real challenge

begins. The prescription must somehow reach a pharmacy, and the medicine must then be sent back to the patient. This process can take days, especially if boats run only a few times a week or if bad weather stops transportation.

Experts in remote healthcare note that delayed access to medicine is one of the most pressing issues facing island communities. In some cases, patients with chronic conditions, such as high blood pressure or diabetes, may run out of their regular medication before a new supply arrives.

Some regions have explored practical solutions. Pre-stocking commonly used

medicines at local clinics is one approach. Training community health workers to dispense basic medication under a doctor's supervision is another strategy that has been used in several remote areas.

Technology may also play a growing role. In certain places, authorities are testing drone delivery systems to bring small packages, including medicines, to locations that are hard to reach by road or sea.

Healthcare planners say that no single solution works everywhere, and that local conditions, regulations, and resources must all be considered when designing systems for remote communities.

Empty Containers Pile Up at Ports Worldwide

By Daniel · 2026-09-28 · 298 words · L3

항구에 쌓인 빈 컨테이너

Millions of empty shipping containers are sitting idle at ports around the world, creating a growing problem for global trade. Instead of returning to the factories and farms that need them, these containers are stuck in the wrong places — sometimes thousands of kilometers from where they should be.

A standard shipping container is a large steel box used to move goods across oceans. Once a ship unloads its cargo at a destination port, the empty containers need to be sent back to export countries so they can be filled again and reused.

However, this return process has broken down in many regions. During the surge in consumer demand following the COVID-19

pandemic, ships rushed to deliver goods but did not always wait to reload empties before departing. This left enormous numbers of containers sitting at receiving ports in Europe and North America.

At the same time, major export nations in Asia — particularly China — were running short of containers needed to ship new goods. Shipping companies reported that finding an available container had become unexpectedly difficult, which pushed freight costs dramatically higher.

The imbalance grew worse because container ships follow fixed routes and schedules. Shipping lines often found it more profitable to send a ship back to Asia

empty than to wait for the empties to be collected and returned properly.

Experts point to a broader problem in global logistics: when one part of the system slows down, the effects spread quickly across the entire supply chain. Ports in Vancouver, Rotterdam, and Shanghai all reported serious congestion during peak disruption periods.

Addressing the container imbalance requires better coordination between shipping lines, port operators, and exporters. Industry analysts say that smarter tracking technology and more flexible scheduling could help prevent similar bottlenecks from developing in the future.

Mapping the Heat Hidden Inside Our Cities

By Daniel · 2026-09-28 · 276 words · L2

도시의 열섬을 재는 사람들

Walk two blocks in any major city on a hot summer day, and the temperature can shift noticeably. One street bakes under direct sun, while the next, shaded by trees, feels several degrees cooler. This is the urban heat island effect — a well-documented pattern in which cities are significantly warmer than the surrounding countryside.

The cause is largely structural. Concrete, asphalt, and steel absorb heat during the day and release it slowly at night. Buildings block wind that would otherwise cool the streets. Green spaces and bodies of water, which help regulate

temperature, are far less common in dense urban areas than in rural ones.

For years, researchers measured city temperatures using weather stations placed at airports or on rooftops. But these readings missed the enormous variation between neighborhoods. A low-income district with little shade might be 7 to 10 degrees Celsius hotter than a wealthier, tree-lined area just a short distance away.

New sensor networks are changing how scientists gather this data. Small, affordable devices can now be mounted on lamp posts, buses, or buildings to record temperature at street level across

an entire city. Projects in cities across Europe, Asia, and North America have begun using these tools to build detailed heat maps that show exactly where the risks are greatest.

The data is already guiding local decisions. City planners use heat maps to prioritize where to plant trees, install shade structures, or resurface roads with cooler materials. Researchers note that targeted cooling measures in the hottest spots can reduce heat-related illness significantly. As climate change pushes summer temperatures higher, understanding urban heat at the neighborhood level is becoming an essential planning tool.

Old EV Batteries Fill Up Storage Warehouses

By Daniel · 2026-09-28 · 144 words · L1

중고 배터리가 모이는 창고

As electric vehicles become more common, a new challenge is growing quietly: what happens to old batteries? When an EV battery can no longer power a car reliably, it still holds a significant amount of energy. These used batteries are now filling up warehouses around the world.

Collecting and storing old EV batteries is not simple. They are heavy, sometimes chemically unstable, and require careful handling. Many salvage yards and recycling companies are building special facilities

just to hold these batteries safely before they are processed.

The goal is to either reuse or recycle the materials inside. Batteries contain valuable metals such as lithium, cobalt, and nickel. Recovering these materials reduces the need to mine new ones. Some companies are even giving old batteries a 'second life' as energy storage systems for homes or buildings — a use that could last several more years.
